Abstract— Background: Vitiligo is an acquired depigmenting skin disorder that can affect the patients' quality of life (QOL). Objectives: The aim of this study was to evaluate the QOL in patients with vitiligo.

Patients and Methods: This study included 30 patients with vitiligo. All the patients filled out questionnaires Skindex- 29. Data were compiled and analyzed statistically.

Results: Among the 30 vitiligo patients, 73,3 % were women and 26,7 % were men. Mean age of patients were 40.53 \pm 12. 91 years old. The mean duration of vitiligo was 9.07 \pm 7.643 years. The mean total Skindex-29 score of the subjects was 24.68 \pm 7,72. There was significant difference according to age's group (p = 0,035) and sex (p = 0,01) but there is no significant difference according to duration of disease's group (p = 0,582).

Conclusions: The study findings showed that vitiligo has a significant effect on the patients' QOL. It seems counselling is needed as part of treatment in vitiligo patients.

Keywords— Vertiligo, Quality of life; Skindex-29

I. INTRODUCTION

A healthy normal skin is essential for a person's physical and mental well being. It is an important aspect of their sexual attractiveness, a sense of well being and a sense of self confidence. 1 Vitiligo is a common condition seen in a dermatology office, which has a variety of comorbidities. Worldwide, the prevalence of vitiligo ranges from 0.4 to 2.0 %, with regions of greater or lesser prevalence.² Jusuf and Meher based on medical records found in 2012 total vitiligo patients were 18,09% of total visits in Cosmetic Division of Outpatient Dermatology and Venereology Clinic in H. Adam Malik General Hospital Medan, in 2013 were 9,21%, 2014 were 8,53% and 2015 were 8,45%.³ Most studies demonstrate slightly greater prevalence in females.² Vitiligo is a common depigmenting skin disorder, characterized by acquired, idiopathic, progressive,

circumscribed hypomelanosis of the skin and hair, with total absence of melanocytes microscopically.⁴ Vitiligo is an important skin disease having major impact on quality of life of patients, many of whom feel distressed and stigmatized by their condition.¹ The psychosocial aspects of vitiligo can be described by stress as a potential cause or effect of the disease, the anxiety or depression of vitiligo patients, or the impact of vitiligo on patient quality of life.⁵ In a research conducted by Hamdani and Jusuf found pigmentation disorder on face were greatly affecting (54,0%) quality of life in subjects at 21 Posyandu in Medan Labuhan.⁶

II. METHODOLOGY

This Patient with confirmed diagnosis of vitiligo were included in this study. Our sampling method was consecutive sampling. Inclusion criteria were diagnosis of vitiligo by a dermatologist and 18 years or above. Exclusion criteria included diagnosis of skin diseases other than vitiligo, other chronic disease or any conditions that might have an effect on QOL, and apparent disability. The study was conducted in the Dermatology Outpatient Clinic of H. Adam Malik General Hospital Medan, Indonesia from June 2016 to September 2016. Those who were referred to the clinic and met the eligibility criteria were recruited. Each subjects were explained about the study and asked to answer the questions in Skindex-29. This tool inquires about how often (never, rarely, sometimes, often, all the time) during the previous 4 weeks the patient experienced the effect described in each item.

Seven items address the symptoms domain, 10 items the emotional domain, and 12 items the functioning domain. All responses are transformed to a linear scale of 100, varying from 0 (no effect) to 100 (effect experienced all the time). Skindex scores are reported as three scale scores, corresponding to the three domains; a scale score is the average of a patient's responses to items in a given domain.⁷ All data from subjects then were analyzed statistically.

III. RESULTS

Among the 30 vitiligo patients, 8 patients were men and 22 were women. Most patients were 40-49 years old (40%) with mean age was 40.53 ± 12.91 years old. 40% of participants had vitiligo for 1-5 years with mean duration of vitiligo was 9.07 ± 7.643 years. Most subjects were working as private employee and finishing high school (Table 1). Based on categorization of total scores, most patients were in moderately affected category (70%) (Table 2). The mean total skindex-29 score of the subjects was $24.68 \pm 7{,}72$ (Table 3). There is significant difference according to age (p = 0.035) and sex (p = 0.01) but there is no significant difference according to duration of disease (p = 0,582). According to age category, the highest mean total score was found in <20 years old group -(35.00 ± 0.00) and based on gender, female attained higher mean score (27,13 \pm 7,55) than male (17.95 ± 2.31) (Table 4).

TABEL 2
DISTRIBUTION OF SUBJECTS BASED ON DEMOGRAPHIC AND CLINICAL CHARACTERISTICS

Variable	n	%
Age (years old)		
<20	1	3,3
20- 29	6	20
30- 39	18	36
50- 59 years	16	32
60- 69 years	4	8
70- 79 years	1	2
Sex		
Female	22	73,3
Male	8	26,7
Education		
Elementary	3	10
Junior high school	2	6,7
Senior high school	14	46,7
University	11	36,7
Occupation		
Civil Officer	4	13,3
Enterprenuer	7	23,3
Private employee	11	36,7
Unemployment	12	24
Duration of disease (years)		
1-5	12	40
6-10	6	20
11-15	7	23,3
16-20	4	13,3
>20	1	3,3

TABEL 2 DISTRIBUTION OF SUBJECT BASED ON TOTAL SKINDEX-29 SCORE CATEGORIZATION

Total Score	Category	n	%
<5	Very little	0	0
6-17	Mild	9	30
18-36	Moderate	21	70
≥37	Severe	0	0

Distribution quality of life scores in this study showed 38 (76%) subjects had a very high quality of life and 12 (24%) subjects had a high quality of life and we didn't find a moderate or low quality of life score in all subjects (Table. 2), furthermore based on the characteristics of the skin tag lesions we also didn't find a significant difference in the quality of life score from all subject (table 4).

TABEL 3.
TOTAL SCORE OF SKINDEX-29

	n	Minimum	Maximum	Mean	Std. Deviation	
Total Score	30	16.70	35.00	24.6800	7.7224	

TABEL 4 DISTRIBUTION CATEGORY OF QUALITY OF LIFE

Variable	Mean of total	P
	$score \pm SD$	
Sex		
Male	$17,95 \pm 2,31$	0,001
Female	$27,13 \pm 7,55$	
Age (years old)		
<20	$35,00 \pm 0,00$	
20-29	$31,95\pm7,47$	
30-39	$21,70\pm0,00$	
40-49	$20,84\pm5,18$	0,035
50-59	$16,70\pm9,15$	
≥60	$24,68\pm0,00$	
Duration of		
Disease (years)		
1-5	$23,64 \pm 7,69$	
6-10	$23,08 \pm 6,17$	
11-15	$25,97 \pm 8,69$	0,582
16-20	$28,68\pm8,83$	
≥20	16,70±0,00	

IV. DISCUSSION

Vitiligo considerably influences the psychological well-being of patients. Disease-induced disfigurement can cause patients to experience a high level of stigmatization, which can lead to psychosocial stresses and negative impacts on quality of life (QOL).⁸ Vitiligo is a multi-factorial pigmentary skin disorder. Recently, the importance of emotional and psychological issues is proposed in incidence, progression, relapse and remission of vitiligo. There are limited studies conducted in developing countries, which assess life quality of patients with vitiligo.⁹

Kim et al in Korea conducted a study regarding the impact of vitiligo in patient' life with similar tool. This study was involving one hundred and thirty-three vitiligo patients and 112 patients with mild skin disorders. They found the symptom scale of Skindex-29 was significantly lower in vitiligo patients than in controls, but the function scale and the emotion scale were significantly higher in the vitiligo group than in controls. However, the difference in function scales between groups was significant in female patients, but not in

male patients. Several clinical profiles, such as duration of disease, severity scores and previous history of treatments, showed close correlations with the function scale. Family history of vitiligo, Köebner phenomenon, patients' perspectives on disease prognosis, and discordance of the severity scores between physicians and patients also influenced the Skindex-29 subscales differently. In their conclusion, the study suggests that patients with vitiligo were highly affected in the functional and emotional aspects of QOL, with some sex differences and perhaps various clinical features may play an important role in the QOL of vitiligo patients.⁸

Study by Ghaderi and Saadatjo in Iran involved 70 patients with vitiligo. All the patients filled out two questionnaires: Short Form 36 (SF-36) and Dermatology Life Quality Index (DLQI). The mean score of patients with vitiligo on DLQI scale was 8.40 ± 5.76 (range, 0-23). Although males scores on SF-36 scale was higher than females, the difference was not statistically significant. With regard to age, the mean total score of SF-36 indicated insignificant differences among age groups. Their findings showed that vitiligo has a significant effect on the patients' QOL. 10

Hedayat et al conducted a study on 25 patients as a pilot and another 173 patients as the main study group, in Razi Hospital, Tehran, Iran, 2013–2014. Persian version of Vitiligo Quality of Life index (VitiQoL) was developed backward-forward method. The Vitiligo Area and Index (VASI), VitiQoL, relationship, demographic and clinical characteristic of patients were measured. The Mean and standard deviation of the VitiQoL score was 30.5 ± 14.5 (range 0-60 in Persian version). They found a significant relationship between VASI score and VitiQoL (p = 0.015, r = 0.187. Based on behavior factor, female patients had poorer quality of life (p = 0.02). Concomitant psychiatric problems, e.g. anxiety and depression, were not associated with QOL; however, they were near to being meaning (p =0.06, r =0.14).

A study by Karia et al tried to determine the psychiatric morbidity and the QOL in patients suffering from vitiligo and to determine the factors related with psychiatric morbidity and those

affecting the OOL in vitiligo patients. 50 patients of age range 18 - 65 years with disease duration of 1-26 years attending the vitiligo clinic in dermatology outpatient department of a tertiary care hospital were included and 50 persons with dermatological or diagnosed psychiatric illness accompanying them served as control group. They found 30% patients in vitiligo group suffered from psychiatric disorder, depression was present in 20% of patients and 8% had anxiety disorder. Thus it found that vitiligo patients had more psychiatric comorbidities as compared to control group and it had bearing on their quality of life too.11

Vitiligo is an acquired depigmentary skin disorder characterized by white macules on the skin associated with social stigma. Vitiligo has major impact on the quality of life due its high cosmetic value, chronic nature of disease and long term ineffective treatments. Vitiligo patients suffer from low self-esteem and poor body image that affects their emotional and psychological well-being. To investigate quality of life of v itiligo patients, psychological impact of unpredictable course of disease and long term treatment among South Indian population Mateen et al conducted a study involving a total of 155 vitiligo patients who were undertaking treatment in dermatology clinic at the Central Research Institute of Unani Medicine. They found patients with vitiligo averaged at about 27.4% of maximum psychological impairment measured by the Dermatology Quality of Life Index (DQLI) summary score. Disability in patients was highest in treatment category with 54.6% impairment followed by symptoms and feelings (41.83%). Dark skin, unmarried, slow responders to the treatment and those having chronicity more than 5 years showed worse quality of life and had 70%, 61%, 62% and 76.5% of impairment in the treatment front of DLQI respectively when compared to light skin (50%), married (52.5%), rapid responders (26%) and chronicity less than 5 years (52%). There was no significant difference in the quality of life between male and female Vitiligo patients. Their results show that vitiligo patients suffer in all aspects of life especially in treatment aspect of DLQI and psychological impairment strongly affects the social well-being of vitiligo patients. 12

A study group comprised of 54 subjects with vitiligo, 57 with psoriasis and 57 unaffected controls with all subjects were examined and interviewed using the DLQI and Emotional State questionnaires. They found total mean DLOI score in vitiligo was 4.7, compared with 0.6 in healthy controls (p < 0.001) and 13.1 in psoriasis (p <0.001). In vitiligo, females experienced a greater impact on feelings and men experienced a greater impact on relationships. Lower quality of life in vitiligo was associated with active stage of the disease, extension of pigment loss, depigmentation on the hands, and earlier onset of disease. The results demonstrate that vitiligo has less impact on quality of life than psoriasis. This case-control study of fair-skinned subjects demonstrates the low level of disease-related impairment in QOL in vitiligo compared with the severe impairment in QOL in psoriasis. ¹³

In our study we found the mean total skindex-29 score of the subjects was $24.68 \pm 7,72$. According to Nijsten categorization, it fell on moderate category. There is significant difference according to age's group (p = 0,035) and sex (p = 0,01) but there is no significant difference according to duration of disease (p = 0,582). This might be because women and younger people are more concern in appearance than men and older ones.

V. CONCLUSIONS

Vitiligo can affect patient's quality of life because cosmetically disturbing. Counselling may be needed as part of treatment to improve subjects and their families' attitude toward this disease.
